### BACKGROUND

First medical contact (FMC)-to-balloon time is associated with outcome of ST-elevation myocardial infarction (STEMI). We aimed to assess the impact on mortality and the determinants of indirect versus direct transfer to the cardiac catheterization laboratory (CCL) independent of system delays

## **METHODS**

We analyzed data from 2206 STEMI patients consecutively included in a prospective multiregional percutaneous coronary intervention (PCI) registry. The primary endpoint was 1-year mortality. The impact of indirect admission to CCL on mortality was assessed using Cox models adjusted on FMC-to-balloon time and covariables unequally distributed between groups. A multivariable logistic regression model assessed determinants of indirect transfer.

# RESULTS

A total of 359 (16.3%) and 1847 (83.7%) were indirectly and directly admitted for PCI.

Indirect admission was associated with higher risk features, different FMCs and suboptimal pre-PCI antithrombotic therapy.

At 1-year follow-up, 51 (14.6%) and 137 (7.7%) were dead in the indirect and direct admission groups respectively (adjusted-HR 1.73; 95%Cl 1.22-2.45).

The association of indirect admission with mortality was independent of pre-FMC and FMC characteristics.

Older age, paramedics- and private physician-FMCs were independent determinants of indirect admission (adjusted-HRs 1.02 per year, 95%Cl 1.003-1.03; 5.94, 95%CI 5.94 3.89-9.01; 3.41; 95%CI 1.86-6.2, respectively).

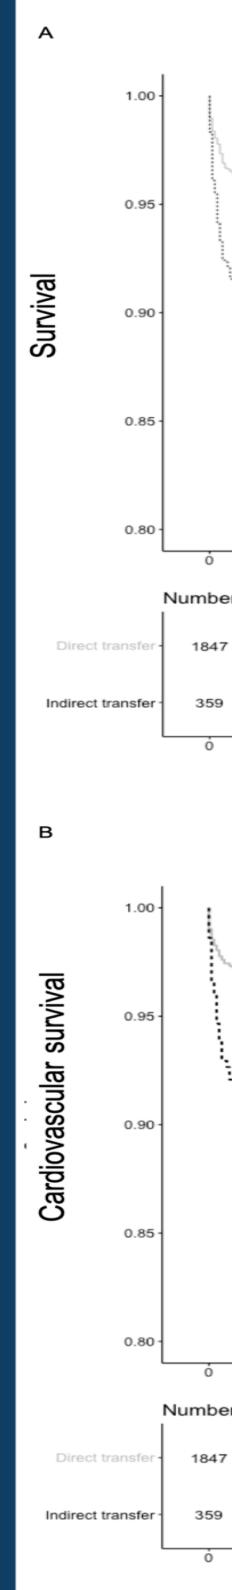

# CONCLUSION

Our study showed that, indirect admission to PCI for STEMI is associated with 1-year mortality independent of FMC to balloon time and should be considered as an indicator of quality of care.

Indirect admission is associated with higher-risk features and suboptimal antithrombotic therapy. Older age, paramedics-FMC and self-

presentation to a private physician were independently associated with indirect admission.

Our study, supports population education especially targeting elderly, more adequately dispatched FMC and improved pre-CCL management.

Indirect transfer to catheterization laboratory for primary PCI for STEMI was associated with 1-Year mortality and cardiovascular mortality independent of system delays and pre-hospital characteristics of the patients
